Czarnota P.: *Japewia tornoensis* and further localities of *J. subaurifera* found in the Carpathians.
Acta Mycol. 44 (2): 259–264, 2009.

Japewia tornoensis is reported for the first time from the Carpathians and Poland. Further localities of *J. subaurifera*, known so far from a single Carpathian collection in the Polish Tatra Mts., are also presented. Some diagnostic features and general distribution of both species are provided and similar taxa are discussed.

Key words: *Japewia*, lichenized fungi, sorediate lichens, Western Carpathians, Poland

INTRODUCTION

The lichen forming genus *Japewia* (Lecanorales, Ascomycota), described recently by Tønsberg (1990) includes only two species, *J. subaurifera* Muhr & Tønsberg and *J. tornoensis* (Nyl.) Tønsberg. From Poland the first one was reported so far. Its single locality in the Polish Tatra Mountains was also known as only one in the whole Carpathians (Bielczyk et al. 2004; Czarnota, Kukwa 2004). The author supposed, however, that the species also occurs in other parts of this Central European mountains, at least in regions covered with upper montane spruce forests. Field investigations carried out in Western Carpathians in 2008–2009 confirmed that suggestion and brought several succeeding records of *J. subaurifera*. Surprisingly, during this intensive work on diversity of epixylic lichens presuming dead spruces, *J. tornoensis* has also been discovered in the Gorce Mts. being a new lichen species for the Carpathians and Poland.

MATERIAL AND METHODS

The material was examined with light microscopes. Hand-made apothecial sections and squashed thallus preparations, were studied in water and potassium hydroxide solution (K). Collections of *J. subaurifera* were compared with other Polish materials checked previously by B. J. Coppins (UK). The material is stored in the Herbarium of the Gorce National Park (GPN). The nomenclature follows *Index Fungorum* (<http://indexfungorum.org>; date of exploration: July 2009) and Liška et al. (2008).

THE SPECIES

Japewia subaurifera Muhr & Tønsberg, Lichenologist 22 (3): 206 (1990).

Morphology and affinities. Descriptions and illustrations of the species are given for example by Tønsberg (1990) and Ohmura & Kashiwadani (1997). All collections presented here correspond well with those descriptions and Tatra's specimens determined previously by Coppins (Czarnota, Kukwa 2004). They are only sterile as most European findings forming brown-yellow, orange-brown to yellowish green soralia (Fig. 1). Because of similarly coloured soralia *J. subaurifera* resembles *Lecidea pullata* (Norman) Th. Fr. and *Caloplaca lucifuga* Thor. It is especially similar to the first species which covers often the same substrates being common in upper montane belt in Carpathians. The second one grows mainly on deciduous trees, particularly often in crevices of rough bark of old *Quercus* spp., rather in lowland woodlands than in mountains. Each of them differ in the chemistry since *J. subaurifera* produces lobaric acid and several 'subaurifera' pigments, *L. pullata* spaerophorin and isosphaeric acid, while *C. lucifuga* has parietin and fallacinal (Tønsberg 1992; Wirth 1995). From those reasons the orange-brown soralia of the last species react K+ red-violet in contrast to K+ fuscous brown soralia of *J. subaurifera* (visible in a squash preparation). Soralia of *L. pullata* give no reaction with K or they are only K ± yellowish.

Ecology. The species grows on bark of several deciduous trees, mainly *Betula* spp., *Alnus incana* and *Sorbus aucuparia* (Tønsberg 1992) but except Scandinavia it is found more often on different conifer trees in large woodlands from about sea-level in north-west Norway to upper montane belt in mountains of Central Europe and Japan. In Poland it was collected only in upper montane spruce forest *Plagiothecio-Piceetum* growing as an epiphyte on *Picea abies* and *Pinus cembra* or as an epixyle of hard wood on decorticated spruce trunks. It prefers old, natural stands showing some implication to be an indicator of ecological continuity of these forest ecosystems. Its ecological role was taken into account also in Scottish native pinewoods, where *J. subaurifera* is considered as the 'Bonus' species (Coppins, Coppins 2002). Accompanied taxa for the new Polish findings include: *Calicium trabinellum* (Ach.) Ach., *Chaenotheca* spp., *Elixia flexella* (Ach.) Lumbsch, *Fuscidea pusilla* Tønsberg, *Hypogymnia physodes* (L.) Nyl., *Hypocenomyce caradocensis* (Leight. ex Nyl.) P. James & Gotth. Schneid., *H. scalaris* (Ach.) M. Choisy, *Lecanora conizaeoides* Nyl. ex Cromb., *L. phaeostigma* (Körb.) Almb., *L. pulicaris* (Pers.) Ach., *L. subintricata*

(Nyl.) Th. Fr., *Lecidea leprariooides* Tønsberg, *L. nylanderi* (Anzi.) Th. Fr., *L. turgidula* Fr. and *Mycoblastus sanguinarius* (L.) Norman.

World distribution. *J. subaurifera* is a widespread lichenized fungus reported mainly from the zone of boreal forests in the Northern Hemisphere. It is especially frequent in Scandinavia; particularly in Norway and Sweden (Tønsberg 1990). From other European sites, including Scotland, Iceland, Komi Republic in Russia, Estonia and mountainous areas of Portugal, the Czech Republic (Šumava, České Švýcarsko, Eastern Sudetes), Austria and Turkey it is known from sparse localities (Boom van den, Giralt 1996; Kristinsson 1999; Palice 1999; Halonen et al. 2000; Tønsberg et al. 2001; Czarnota, Kukwa 2004; Halda 2006). *J. subaurifera* seems to be also widespread throughout boreal zone of North America (Tønsberg 1990, 1992; McCune et al. 2000; Hauck et al. 2006); its locally frequent occurrence on Japan island Hokkaido is also known (Ohmura, Kashiwadani 1997). Up to date the single locality from Polish Tatra Mts. was considered as only one in whole Carpathians (Czarnota, Kukwa 2004). The new findings presented here extend its occurrence on other ranges of Western Carpathians.

SPECIMENS EXAMINED (all within upper montane spruce forest *Plagiothecio-Piceetum*). POLAND. ATPOL grid square **Gd 27** – Western Beskid Mts., Babia Góra Massif, Babia Góra National Park, NE slope of Sokolica Mt., 49°35'10.4"N, 19°34'06.5"E, alt. 1250 m, on wood of decorticated trunk of *Picea abies*, 8 June 2009, leg. P. Czarnota 5976 (GPN) and 49°35'08.8"N, 19°34'07.9"E, alt. 1275 m, on bark of *Picea abies*, 8 June 2009, leg. P. Czarnota 5981 (GPN). **Ge 11** – Western Beskid Mts., Gorce Mts., Gorce National Park, forest section no. 8c, N slope of Kudłoń Mt., 49°34.448"N, 20°10.583"E, alt. 1210 m, on wood of *Picea abies*, 18 May 2009, leg. P. Czarnota 5986 (GPN). **Ge 21** – Gorce Mts., Gorce National Park, forest section no. 184b, W of Gabrowska glade, 49°32.595"N, 20°08.510"E, alt. 1245 m, on bark of *Picea abies*, 29 Aug. 2008, leg. P. Czarnota 5632 (GPN).

Japewia tornoensis (Nyl.) Tønsberg – Lichenologist 22 (3): 206 (1990).

Syn. *Lecidea tornoensis* Nyl., Herb. Mus. Fenn.: 110 (1859); *Biatora tornoensis* (Nyl.) Th. Fr., Nova Acta R. Soc. Scient. upsal. 3: 296 (1861); *Mycoblastus tornoensis* (Nyl.) R. A. Anderson, Bryologist 77 (2): 220 (1974).

Morphology and affinities. Considering similar lichens growing in the upper montane belts of Western Carpathians, *J. tornoensis* at first sight resembles paler (shaded) forms of *Strangospora moriformis* (Ach.) Stein by semiglobose, immarginate, brown to dull brown apothecia (Fig. 2). Mature apothecia of *Lecanora phaeostigma* with reduced excipulum are also very similar to those formed by *J. tornoensis* (Fig. 3). Growing closely to the both species, *J. tornoensis* could easily be overlooked thus its real distribution in the Carpathians seems to be wider than we currently known. Its distinguishing from the latter species is quite simple by anatomic characters, mainly by distinct differences in ascus shape and strongly thickened spores (walls 1.5–3 μ m), which are large (15–20 × 10–15 μ m) and additionally coated by thick gelatinous episporule (Figs 4, 5). *L. phaeostigma* has much smaller, ellipsoid and thin-walled spores and moreover very often visible numerous brown black pycnidia. *S. moriformis* forms globose, small ascospores and multisporous ascii. For more details see for example Tønsberg (1990) and Hawksworth & Coppins (1992).

Ecology. Except Antarctica and oceanic parts of Europe, where *J. tornoensis* has been found on terricolous bryophytes and humus in rock crevices (Hawksworth, Coppins 1992; Olech 2004), almost all its inland reports are made in subalpine belts covered with conifer forest. It was collected there mainly as an epiphyte on, e.g.,

Larix decidua, *Pseudotsuga manziesii*, *Picea engelmannii*, *Abies lasiocarpa* and rarely on wood.

Studies of Hauck and Spribille (2005) in spruce-fir forests of northwestern Montana suggest that *J. tornoensis* principally occupies branches of conifer trees. Perhaps the species prefers the same kind of habitat also in the Carpathians, as would indicate the finding presented here.

World distribution. *J. tornoensis* is a widespread bipolar species, however except Arctic regions is rather rarely reported elsewhere. It is known from Austria (Alps; e.g. Obermayer 1997; Hafellner et al. 2003), Germany (Bayern; Scholz 2000), whole Scandinavia (Santesson 2004) including Svalbard (Elvebakk, Hertel 1997), Switzerland (Scheidegger et al. 2002), British Isles (C Scotland; Hawksworth, Coppins 1992), Iceland, Greenland, Canada, Alaska, almost all geographical regions of Arctic Russia (Thomson 1997; Kristinsson et al. 2006), Mongolia (Hauck, Javkhlan 2008), Japan (Kurokawa 2003), USA: e.g., Colorado (Anderson, Carmer 1974), Arizona (Obermayer 1997), New York (Harris 2004), Montana (Hauck, Spribille 2005) as well as Antarctica (Øvstedral, Lewis Smith 2001; Olech 2004).

SPECIMEN EXAMINED. POLAND. Ge 21 – Western Beskydy Mts, Gorce Mts., Gorce National Park, forest section no. 158a, E of Jaworzyna Kamienicka Mt., 49°32.794'N, 20°09.901'E, alt. 1250 m, on hard wood of spruce branch within upper montane spruce forest *Plagiothecio-Piceetum*, 2 Oct. 2008, leg. P. Czarnota 5637 (GPN), det. Z. Palice.

Acknowledgements. Dr. Z. Palice (Průhonice, Czech Republic) is thanked for turn my attention towards *J. tornoensis* and his hospitality during my stay in Průhonice in 2009. The work is a part of project supported by Polish Ministry of Science and Higher Education, grant no. N N304 306835.

Japewia tornoensis i kolejne stanowiska *J. subaurifera* odnalezione w Karpatach

Streszczenie

Rodzaj *Japewia* (grzyby zlichenizowane) obejmuje dwa gatunki, *J. tornoensis* i *J. subaurifera*. Pierwszy, o bipolarnym charakterze występowania na świecie, został stwierdzony po raz pierwszy w Karpatach (Gorce) i w Polsce. Drugi, znany przede wszystkim z borealnych obszarów Półkuli Północnej, notowany był dotychczas w Karpatach tylko na jednym stanowisku, w Tatrach (Czarnota, Kukwa 2004). Teraz odnaleziono go także w Gorcach i na Babiej Górze. Oba gatunki w całej Europie Środkowej są uznawane za rzadkie.

J. subaurifera występuje przede wszystkim w postaci płonnej, wykształcając charakterystyczne, brunatnawoźłe, pomarańczowobrunatne lub zielonawoźłe soralia produkujące kwas lobariowy i kilka pigmentów „subaurifera” (m. in. secalonic acid i eumitryn). W Karpatach Zachodnich gatunek ten rośnie na korze starych świerków i na twardym drewnie pni świerkowych w górnoreglowym borze świerkowym *Plagiothecio-Piceetum*. Lokuje się ponad podstawą pnia, zajmując tym samym odmienną niszę ekologiczną niż *Lecidea pullata* – inny, morfologicznie podobny, „sorediowany” i częsty w tym zbiorowisku leśnym grzyb zlichenizowany.

J. tornoensis wykształca półkoliste, brunatnoczerwone apotecja przypominające wyglądem jaśniejsze (ocienione) formy *Strangospora moriformis*, a także *Scoliciosporum chlorococcum* czy też *Lecanora phaeostigma*. Gatunek ten łatwo jest odróżnić po charakterystycznych, grubościennych (1,5–3 μ m), jednokomórkowych, dużych zarodnikach (15–20 x 10–15 μ m). Podobieństwo do tych pospolitych porostów pozwala przypuszczać, że może to być gatunek częstszy w Karpatach, lecz przeoczany.
